## Where Does a Llama Live?

Llamas are fascinating animals that live in specific parts of the world. They are native to South America and are commonly found in countries like Peru, Bolivia, Ecuador, and Chile. Llamas thrive in the Andes Mountains, where the air is thin and the temperatures can be quite cold. This mountainous region provides the perfect habitat for llamas due to its cool climate and grassy terrain.

Llamas prefer to live in high-altitude environments where they can graze on grasses and shrubs. They are well-adapted to this type of habitat because their thick wool keeps them warm, and their strong legs help them navigate rocky paths. Llamas are often seen in open grasslands, but they can also be found in plateaus and valleys within the mountain ranges.

Although llamas are native to South America, they have been introduced to other parts of the world as well. People in North America, Europe, and Australia now raise llamas for their wool and as pack animals. They can adapt to different habitats, but they do best in cooler climates with plenty of space to roam.

Llamas are herbivores, meaning they eat only plants. Their natural diet includes grasses, herbs, and shrubs. This makes their grassy mountain habitats ideal, as food is plentiful and they can graze throughout the day.

In summary, llamas prefer to live in cool, high-altitude regions like the Andes Mountains. Their thick wool and strong legs make them perfect for this environment. While they are mainly found in South America, they can also thrive in other parts of the world with similar conditions.
